

Two minutes. Two decisions. One standard of proof.

A screen-recording script built around real OHRC and TMC-2 audits. The visible IIRS catalogue footprint remains an unverified pixel-registration candidate.

Opening line

A glowing overlap on the Moon can be wrong. Point to the three sensor options, then make the judges challenge the evidence.

0:00–1:14 / Candidate to registered local region

TIME	SHOW / CLICK	SAY
0:00–0:15 — Problem	Start at http://127.0.0.1:8000/ . Keep the full Moon visible and let it rotate. Point across the top OHRC → TMC-2 → IIRS options without clicking them.	OHRC is our microscope at roughly 25 centimetres per pixel. TMC-2 is the terrain bridge at five metres. IIRS records infrared spectra around eighty metres. Same Moon, three different languages—and an apparent overlap can lie.
0:15–0:26 — Candidate search	Click Triple overlap in the top bar. Let the gold catalogue rings appear. Click Pause rotation so the audited markers stay still. Point briefly to the gold rings, then the green AUDITED OHRC/TMC marker near the lower centre.	These rings are search candidates, not verified registrations. We separate catalogue geometry from evidence on real image pixels.
0:26–0:41 — Real imagery	Click the green AUDITED OHRC/TMC marker. Wait for the zoom. At the bottom-left of the Moon panel, click TMC-2 ortho , then OHRC browse to show the two actual products on the globe.	This is our real OHRC–TMC-2 pair. Here are the actual OHRC browse and TMC ortho images. The science-pixel test is the next step.
0:41–0:55 — Report	Click Scientific verification above the Moon. Let the Moon slide left and the evidence panel appear. Point to the exact product IDs, REGISTERED · LOCAL , and the embedded AUDIT REPORT . Scroll *inside the white report pages* just enough to show its table and real-data figure.	The decision is attached to exact product IDs and a reproducible audit. It says registered only for this middle region—never the whole OHRC strip or absolute ground accuracy.
0:55–1:14 — Independent matchers	Move the cursor to the dark right margin outside the white report and scroll the evidence panel down to SIFT / AKAZE . Show SIFT’s held-out result, then click AKAZE . Pause on the numbers and inlier image.	On frozen held-out locations, SIFT accepts 93 of 111 and AKAZE accepts 48 of 56. Both pass the fixed support and coverage gates. Their relative RMSE is 1.30 and 1.44 pixels on the native five-metre TMC grid—not sub-metre lunar accuracy.

Show the system saying no

Finish the live prototype, then hold the rejected verdict on screen. This is the contrast the judges should remember.

TIME	SHOW / CLICK	SAY
1:14–1:26 — Visual check	Click Terrain swipe . Drag its slider from the centre to each side once, slowly.	The swipe lets judges inspect the terrain themselves. The verdict also requires camera and DTM support, spatial spread, reverse checks, and rejected wrong-location controls.
1:26–1:39 — The trap	Click ✖ at the top-right of the evidence panel, then Zoom out above the Moon. Click the pink REJECTED OHRC/TMC PAIR marker above the green one. Wait for zoom, then click Scientific verification .	Now try a second pair that looks plausible on the map. LunaCorr challenges it by the same rules.
1:39–1:54 — Rejection	Point to REJECTED · CONSISTENCY and the embedded two-page report. Scroll *inside the report pages* to its test table, then point to the failed evidence gates below if visible.	SIFT has zero of six held-out inliers. AKAZE reaches 25 of 50, but covers only 9.3 percent—below the 15 percent gate. Independent terrain alignment disagrees with the image shift. We accept zero control points.
1:54–2:00 — Impact	Leave the rejected verdict and report on screen. Do not switch to an untested triple.	LunaCorr makes every overlap defend its claim—or refuses to register it.

If a judge asks about IIRS

Use this exact boundary

IIRS records infrared spectra at roughly 80 m per pixel across about 256 bands. Its footprint candidates appear on the globe, but no TMC-2-to-IIRS science-pixel registration is certified in this demo. Fine OHRC craters cannot be recovered by enlarging IIRS pixels. The next leg must pass geometry-bounded structural matching and independent checks; until then, LunaCorr abstains.

Recording checks

Record at 1080p or higher with clear narration. Show the registered and rejected result for at least three seconds each. Scroll inside the white report to inspect its pages; scroll the dark panel margin to reach SIFT/AKAZE. If time runs long, omit Terrain swipe but preserve both decisions and held-out numbers.

Claim boundary: REALPAIR005 is relative local OHRC-to-TMC-2 registration on the native 5 m TMC ortho grid. REALPAIR001 is rejected with zero accepted science control points. Catalogue triple-overlap rings do not prove OHRC-TMC-2-IIRS registration.
